

Fundamentals and Machine Model

Machine/Memory Model and the Function Call Stack

Object: a piece of data that's stored at a particular location in memory during runtime.

Variable: a *name* in source code that is associated with an object at compile time.

❗ Not all objects are associated with variables; e.g. dynamically-stored objects and string literals are not.

❗ The value stored by a variable's memory object may change, but the association between a variable and an object itself can only change when the variable goes out of **scope**.

Static objects "live" for essentially a program's runtime. Local objects' lifetimes are tied to scope (e.g. a block of code or pair of curly braces). Dynamic objects are manually created/destroyed.

❗ Objects declared in a loop body (between the {}) are created/destroyed each time the loop repeats.

Atomic (primitive) types: types whose objects can't be subdivided into smaller objects; includes `int`, `double`, `bool`, `float`, `char`, and all pointer types. Atomic objects are default-initialized to undefined values.

```
1 // Four different ways to initialize an int to 5
2 int a = 5; int b(5); int c{5}; int d = {5};
1 // Explicitly cast an int 'd' to a double 'e'
2 double e = static_cast<double>(d);
```

Objects in C++ are **statically-typed**. Although an object may evaluate to a different type in an expression, the type of an object itself cannot change (class objects obey this rule too).

The memory allocated to store a function's parameters and local variables during runtime is called a **stack frame** or activation record. The memory frame for the most-recently called function is added to the "top" of the **function call stack** and is destroyed when the function returns ("Last In First Out" ordering).

Procedural Abstraction and Program Design

Procedural Abstraction involves using functions to break down a complex procedure into sub-tasks and separate the interface of a procedure (what it does) from implementation (how it works).

Interface examples: declarations in `.h` files, valid/invalid inputs, RME statements, *signature* (function name and parameter types), return type, and ADT representation invariants.

Implementation examples: definitions in `.cpp` files and code/comments inside function bodies.

Pointers and Arrays

A **pointer** is a type of object that stores another object's memory address as its value.

❗ An `int*` pointer variable can *only* point to an `int`; an `int**` pointer variable can *only* point to an `int*`; and so on. (E.g. attempting to make an `int*` pointer point to a `double` will lead to a compile error.)

Dereferencing a pointer: getting the object at an address. Note that the star `*` operator is used both to declare pointers and to dereference them (similarly, the `&` operator is used both to get an object's address and to declare a reference).

```
1 int x = 3; int y = 4;
2 int *ptr = &x; // ptr initialized to x's address
3 cout << *ptr; // dereferences ptr/prints 3
4 ptr = &y; // no star...assigns y's address to ptr
5 *ptr = 6; // dereferences ptr/assigns 6 to y
```

❗ Assigning `ptr = ptr2`

copies the address stored by `ptr2` to `ptr` (subsequently changing `ptr2` wouldn't change `ptr`).

❗ A reference to a reference is really another reference for the "original" object.

```
1 int x = 5;
2 int* y = &x; // creates pointer to x
3 int* z = y; // creates another pointer to x
4 int &a = x; // creates reference to x
5 int* &b = z; // creates reference to z
6 cout << &b << endl; // Prints 5
7 cout << &y << endl; // prints 0x2714
8 cout << y << endl; // prints 0x2710
9 cout << *&z << endl; // equiv. to cout << &x
10 cout << *&z << endl; // equiv. to cout << z
```

Null pointer: a pointer that holds address `0x0` (which no object can be located at) and implicitly converts to `false`. Any pointer can be null; to do so, set it equal to `nullptr` (0 or `NULL` also work but are bad style).

Common Pointer Bugs/Errors

❗ Dereferencing a default-initialized pointer results in undefined behavior, as (like all atomic objects) pointers that aren't explicitly initialized are default-initialized to an undefined value (*not* `nullptr`).

❗ Dereferencing a null pointer also leads to undefined behavior (almost always a program crash).

❗ If a function returns a pointer or reference to one of its local variables (which die when the function returns), using the reference or dereferencing the pointer produces undefined behavior.

```
1 void swap_pointed(int *x, int *y) {
2     int tmp = *x;
3     *x = *y;
4     *y = tmp;
5 }
6
7 int main() {
8     int a = 1216, b = 1261;
9     swap_pointed(&a, &b);
10 }
```

Pointers vs References

References and pointers both enable working between stack frames (scopes) and indirection. Some ways they're different:

- References *must* be explicitly initialized (unlike pointers). This is because references are aliases for existing objects.
- Pointers must be dereferenced to access the objects they point at, while references are used "as-is".
- You can change the object that a (non-const) pointer points to, while a reference's binding to an object can't be changed.

Arrays and Pointer Arithmetic

Arrays: fixed-size containers that store objects of the same type (and same size) in contiguous memory.

```
1 // Valid array declarations
2 int arr[3] = {1,2}; // {1,2,0}
3 int zeroArr[3] = {}; // {0,0,0}
1 // Valid array declarations
2 int arr[] = {4,5,6};
3 int mat[2][2] = {1,2,3,4};
1 // INVALID array declarations
2 int junk[4]; // Undefined items
3 int err[2][1] = {5,6,7,8}; // No
```

Array decay: using an array in a context where a value is required causes the compiler to convert the array into a pointer to its first element. Array decay is why it's necessary to pass an array's size separately from the array to a function (or to indicate the end of an array with a *sentinel character* like C-strings do).

❗ Dereferencing a pointer that goes past the bounds of an array results in undefined behavior. But merely *using* a pointer that goes just past the end of an array without dereferencing it is well-defined.

```
1 void add_five(int arr[], int size) {
2     for (int i = 0; i < size; i++) { arr[i] += 5; }
3     // arr[i] += 5 is equiv. to *(arr + i) += 5
4
5     int main() {
6         int arr[] = { 10, 20, 30 };
7         add_five(arr, (sizeof(arr) / sizeof(*arr)));
8         cout << arr[1] << endl; // prints 25
9         // i[arr] is equiv. to arr[i], but bad style
```

Passing `arr` by value passes a pointer to `arr[0]` by value. Also, `arr[1]` is shorthand for pointer arithmetic followed by a dereference, i.e., `arr[1] = *(arr + 1)`.

❗ The `sizeof` operator returns the size of an object in bytes. In this example, `sizeof(arr)` alone would return 12, not 3.

```
❗ cout << &arr[0],
cout << arr, and
cout << &arr
would all print
0x1008.
```

```
1 // Mainly for pointers into the same array
2 double arr[4] = { 2.5, 5.0, 8.0, 7.0 };
3 double* ptr1 = &arr[0], *ptr2 = &arr[3];
4 cout << *arr << endl; // prints 2.5
5 cout << (ptr2 - ptr1) << endl; // prints 3
6 cout << (ptr1 - ptr2) << endl; // prints -3
7 (ptr1 > ptr2); // equates to false (0)
8 ptr1 += 2; // ptr1 now points at arr[2]
```

Using the `&` operator on an array produces a pointer to the entire array, not a pointer to the first element or a pointer to a pointer (& does not require a value, so it doesn't cause decay).

```
1 int arr[4] = { 1, 2, 3, 4 };
2 int (*arr_ptr)[4] = &arr; // pointer to entire array
3 cout << (*arr_ptr)[2] << endl; // prints 3
4 // *arr_ptr would increment by the size of 4 ints
```

Traversal By Pointer: arrays can be traversed by pointer (mostly used with C-strings and iterators).

```
Traversal By Pointer: Pattern 1
1 int const SIZE = 3;
2 int arr[SIZE] = { -1, 7, 2 };
3 int *ptr = arr;
4 while (*ptr != 0) {
5     // int* end is just past the end of arr
6     while (ptr < end) {
7         cout << *ptr << endl;
8         ++ptr; // "Walk" ptr across arr
9     } // Alternative to while loop below
1    for (; ptr < end; ++ptr) { ... }
```

```
Traversal by Pointer: Pattern 2 (C-String Sanitization)
1 void sanitize_username(Account *acc, char to_remove) {
2     char *ptr_a = acc->username, *ptr_b = acc->username;
3     while (*ptr_a && *ptr_b) { // while not '\0'
4         if (*ptr_b != to_remove) {
5             *ptr_a = *ptr_b;
6             ++ptr_a; // ++ptr_a only when a char gets copied
7         }
8         ++ptr_b; // ++ptr_b every time the loop executes
9     }
10    *ptr_a = '\0'; // null-terminate string when done
11 }
```

The const Keyword

The `const` type qualifier prevents objects from being modified after initialization (attempting to do so causes a compile error). `const` scalars must be explicitly-initialized to compile.

const pointers: pointers that can modify what they point at but cannot be re-pointed to different objects.

Pointer-to-const: read-only pointers; pointers that can be re-bound but can't modify what they point at.

❗ A const pointer must be initialized to compile, but a pointer-to-const doesn't need to be.

Reference-to-const: a read-only alias.

const array: an array of const elements. Note that the positioning of `const` matters for arrays of pointers.

const Conversions and Passing

The compiler treats every pointer-to-const as if they point to a const object and every reference-to-const as if they're aliased to a const object. It won't allow conversions that could bypass existing const protections (so, for example, you can assign a const pointer to a pointer-to-const, but the converse is *not* true).

```
1 int foo(int* a) { ... }
2 int bar(int b) { ... }
3 int func(const int* c) { ... }
4 const int x = 3;
5 bar(x); func(&x); // both ok
6 foo(&x); // ERROR
```

```
1 const int x = 3;
2 int y = x; // OK
3 const int* cptr = &x; // OK
4 const int& cref = x; // OK
5 int* ptr = cptr; // ERROR 1
6 int& ref = cref; // ERROR 2
1 int x = 2, y = 5;
2 const int *x_ptr = &x;
3 int *y_ptr = &y;
4 *y_ptr = *x_ptr; // OK
5 y_ptr = x_ptr; /* ERROR (even
6 though x isn't const) */
```

- Pass by **pointer/reference**: if you need to modify the original object (as opposed to a local copy).
- Pass by **value**: if an object is small (e.g., an `int`) and you can't/don't need to modify the original.
- Pass by **pointer/reference-to-const**: if you want to pass a large object without modifying it.

Strings, Streams and I/O

Using C-Strings and Strings

```
1 const char* msg = "Welcome!"; // Only works for string literals; use .c_str() on string variables
2 char color[] = "00274C"; // Create 7-element array (including \0) and copy a string literal to it
3 // Note: '\0' is the only char that evaluates to false (useful for traversal-by-pointer loops).
4 cout << cstr << " " << *cstr << " " << &cstr[0] << endl; // prints "abcd aabcd"
5 cout << (cstr + 1) << " " << *(cstr + 1) << " " << *(cstr + 1); // prints "bcd b 98"
6 string xyz = string(cstr); // Explicitly copy cstring to a string (implicit copy would work too)
```

	Length	Copy Value	Index	Concatenate	Compare
<code><cstring></code>	<code>strlen(cstr);</code>	<code>strcpy(cstr1, cstr2);</code>	<code>cstr[1];</code>	<code>strcat(cstr1, cstr2);</code>	<code>strcmp(cstr1, cstr2);</code>
<code><string></code>	<code>str.length();</code>	<code>str1 = str2;</code>	<code>str[1];</code>	<code>str1 += str2;</code>	<code>str1 != str2;</code>

Streams and File I/O

Input redirection	Output redirection	Pipeline	Combined redirection
<code>./main.exe < input.txt</code>	<code>./main.exe > output.txt</code>	<code>./output.exe input.exe</code>	<code>./main.exe < input.in > output.out</code>

```
File I/O Example: Print Lines From File
1 #include <fstream> // defines (if/of)stream objects
2 int main() {
3     ifstream inFS;
4     inFS.open("file.txt"); // valid
5     if (!inFS.is_open()) { return 1; }
6     string my_string; // initialized to empty string
7     while (getline(inFS, my_string)) {
8         cout << my_string << endl;
9     } // could close inFS manually via inFS.close();
10    // inFS also closes when scope ends/main returns
```

```
Ex: Copy One File's Contents to Another
1 #include <fstream>
2 int main() {
3     ifstream inFS("input.txt"); // Also valid
4     ofstream outFS("output.txt");
5     string my_string;
6     // newline and space both "delimit" words
7     while (inFS >> my_string) {
8         outFS << my_string << '\n';
9     } // '\n' is the newline char
10 }
```

istreamstream: a stream that "simulates" input from a hardcoded string.

ostreamstream: a stream that captures output and stores it in a string (use `.str()` to get the string).

```
1 string input = "abc";
2 istreamstream inSS(input);
1 ostreamstream outSS; // (<i>o)stringstream are defined in <sstream>
2 Mat_print(mat, outSS); // Capture output
```

❗ `ifstream`, `istreamstream`, and `cin` can all be passed to a function with an `istream&` parameter. Likewise, `ofstream`, `ostreamstream`, and `cout` can all be passed to a function with an `ostream&` parameter.

Command-Line Arguments

`argc`: an `int` parameter of main representing the number of a command's arguments.

`argv`: functionally, an array of the arguments. Technically, `argv` is passed to `main` as a pointer to an array of pointers to C-strings. So `argv[0]` is a pointer to a C-string that represents the name of the program.

```
1 #include <iostream>
2 #include <string> // includes stoi()/stod()
3 int main(int argc, char* argv[]) { // char** argv also OK
4     if (string(argv[1]) == "add") {
5         int sum = 0;
6         for (int i = 2; i < argc; i++) { sum += stoi(argv[i]); }
7         cout << "Sum: " << sum << " , argc: " << argc << endl;
8     } // pay attention to where the "actual" arguments start
9     // Also remember to use stoi()/stod() when needed
```

```
Terminal
hugokin@ubuntu:~$ ./main.exe add 7 2
Sum: 9, argc: 4
hugokin@ubuntu:~$ ./main.exe add 1 2 3
Sum: 6, argc: 5
hugokin@ubuntu:~$
```

ADTs, Structs and Classes

C-Style Structs and ADTs

A **struct** is a class-type object composed of member subobjects (heterogeneous data). They're passed by value by default, and they support assignment and initialization via the `=` operator. A `struct` or `class` object can also be declared as `const`, which prevents it and all of its data members from being modified.

❗ `const` class-type objects must have their data members initialized (or a runtime error will occur).

❗ A `const` instance of a class or struct cannot call non-const member functions.

Arrow -> operator: shorthand for pointer dereferencing followed by member access. `(*ptr).x` == `ptr->x`;

❗ Without parentheses, the dot and arrow operators have greater precedence than dereferencing.

Abstract Data Type: a data type that separates its behavior and implementation. ADTs encompass both data and behaviors/functions that act upon it. Not all structs are ADTs, some are "plain old data".

❗ Accessing the member data of an ADT directly is said to break the interface and should be avoided. Unit tests should also respect the interface (because they should test behavior, not implementation).

C++ Classes

In C++, the only real difference between classes and structs are that classes have private member access and private inheritance by default (structs default to public access/inheritance).

Constructors

- 1 The compiler implicitly creates a default ctor if there are no user-defined ctors.
- 2 The order in which members are declared in a class is *always* the order they're initialized in.
- 3 Initialization values from a member init. list over-write initializations made during declarations.
- 4 Data members that aren't included in a ctor's member initializer list or initialized at declaration get default-initialized/constructed.
- 5 A delegating ctor must contain a call to the other ctor (and nothing else) in its member init. list.

```
1 class Animal {
2 private: string name;
3 public:
4     Animal(string name_in) // Non-default ctor
5     : name(name_in) { } // Member init. list
6     Animal() // Default ctor (no arguments)
7     : Animal("Blank") { } // ctor delegation
8 }; // Note the semicolon here!
9
10 class Bird : public Animal {
11 private: bool has_wings;
12 public: Bird(string name, bool wings_in)
13     : Animal(name), has_wings(wings_in) { }
14 }; // Derived class ctors must call base ctor
15
16 class Duck : public Bird {
17 private: string color;
18 public: Duck(string name, bool wings, string rgb)
19     : Bird(name, wings, color(rgb) { }
20 }; // Calling Bird ctor also calls Animal ctor
21
22 // This is how to define a ctor OUTSIDE of body
23 Duck::Duck(string name, bool wings, string rgb)
24 : Bird(name, wings, color(rgb) { }
```

Nested Classes and Constructors

To initialize a nested class object, initialize it with a valid argument for the nested class's ctor.

Nested class objects in a const class object are also const.

```
1 class Book {
2 public:
3     Book(double price_in)
4     : price(price_in) { }
5 // Note: no default Book ctor
6 private:
7     double price;
8 };
9
10 class Person {
11 public:
12     Person(string& n, double p)
13     : name(n), favBook(p) { }
14 private:
15     string name;
16     Book favBook;
17 };
18
19 class Bird {
20 public:
21     Bird(string name, bool wings, string color)
22     : Animal(name, wings, color) { }
23 };
24
25 class Duck {
26 public:
27     Duck(string name, bool wings, string color)
28     : Bird(name, wings, color) { }
29 };
30
31 class Animal {
32 public:
33     Animal(string name, bool wings, string color)
34     : Bird(name, wings, color) { }
35 };
36
37 class Bird {
38 public:
39     Bird(string name, bool wings, string color)
40     : Animal(name, wings, color) { }
41 };
42
43 class Duck {
44 public:
45     Duck(string name, bool wings, string color)
46     : Bird(name, wings, color) { }
47 };
48
49 class Animal {
50 public:
51     Animal(string name, bool wings, string color)
52     : Bird(name, wings, color) { }
53 };
54
55 class Bird {
56 public:
57     Bird(string name, bool wings, string color)
58     : Animal(name, wings, color) { }
59 };
60
61 class Duck {
62 public:
63     Duck(string name, bool wings, string color)
64     : Bird(name, wings, color) { }
65 };
66
67 class Animal {
68 public:
69     Animal(string name, bool wings, string color)
70     : Bird(name, wings, color) { }
71 };
72
73 class Bird {
74 public:
75     Bird(string name, bool wings, string color)
76     : Animal(name, wings, color) { }
77 };
78
79 class Duck {
80 public:
81     Duck(string name, bool wings, string color)
82     : Bird(name, wings, color) { }
83 };
84
85 class Animal {
86 public:
87     Animal(string name, bool wings, string color)
88     : Bird(name, wings, color) { }
89 };
90
91 class Bird {
92 public:
93     Bird(string name, bool wings, string color)
94     : Animal(name, wings, color) { }
95 };
96
97 class Duck {
98 public:
99     Duck(string name, bool wings, string color)
100    : Bird(name, wings, color) { }
101 };
102
103 class Animal {
104 public:
105     Animal(string name, bool wings, string color)
106     : Bird(name, wings, color) { }
107 };
108
109 class Bird {
110 public:
111     Bird(string name, bool wings, string color)
112     : Animal(name, wings, color) { }
113 };
114
115 class Duck {
116 public:
117     Duck(string name, bool wings, string color)
118     : Bird(name, wings, color) { }
119 };
120
121 class Animal {
122 public:
123     Animal(string name, bool wings, string color)
124     : Bird(name, wings, color) { }
125 };
126
127 class Bird {
128 public:
129     Bird(string name, bool wings, string color)
130     : Animal(name, wings, color) { }
131 };
132
133 class Duck {
134 public:
135     Duck(string name, bool wings, string color)
136     : Bird(name, wings, color) { }
137 };
138
139 class Animal {
140 public:
141     Animal(string name, bool wings, string color)
142     : Bird(name, wings, color) { }
143 };
144
145 class Bird {
146 public:
147     Bird(string name, bool wings, string color)
148     : Animal(name, wings, color) { }
149 };
150
151 class Duck {
152 public:
153     Duck(string name, bool wings, string color)
154     : Bird(name, wings, color) { }
155 };
156
157 class Animal {
158 public:
159     Animal(string name, bool wings, string color)
160     : Bird(name, wings, color) { }
161 };
162
163 class Bird {
164 public:
165     Bird(string name, bool wings, string color)
166     : Animal(name, wings, color) { }
167 };
168
169 class Duck {
170 public:
171     Duck(string name, bool wings, string color)
172     : Bird(name, wings, color) { }
173 };
174
175 class Animal {
176 public:
177     Animal(string name, bool wings, string color)
178     : Bird(name, wings, color) { }
179 };
180
181 class Bird {
182 public:
183     Bird(string name, bool wings, string color)
184     : Animal(name, wings, color) { }
185 };
186
187 class Duck {
188 public:
189     Duck(string name, bool wings, string color)
190     : Bird(name, wings, color) { }
191 };
192
193 class Animal {
194 public:
195     Animal(string name, bool wings, string color)
196     : Bird(name, wings, color) { }
197 };
198
199 class Bird {
200 public:
201     Bird(string name, bool wings, string color)
202     : Animal(name, wings, color) { }
203 };
204
205 class Duck {
206 public:
207     Duck(string name, bool wings, string color)
208     : Bird(name, wings, color) { }
209 };
210
211 class Animal {
212 public:
213     Animal(string name, bool wings, string color)
214     : Bird(name, wings, color) { }
215 };
216
217 class Bird {
218 public:
219     Bird(string name, bool wings, string color)
220     : Animal(name, wings, color) { }
221 };
222
223 class Duck {
224 public:
225     Duck(string name, bool wings, string color)
